

Exercises with Files

These exercises are designed to increase familiarity with the basic syntax of reading and writing with files.

- `open()` function. `close()` method
- `read()`, `readline()`, `readlines()` methods
- `write()` method

Create the following Python programs:

1. In your class folder is a file called "names.txt" Create a program that reads from the names file and simply says hello to each person, but only call them by their first name
2. The format of "absence.txt" is <name>,<daysAbsent>
Write a program that will read from "absence.txt" and calculate the total of all absences. Also, create another file named "output.txt" that will have only the students with 5 or more absences.

e.g.
John,7
Peter,14

would be the output in this case.

3. Read from words.txt and create a list with number of words in each row. (How many words are in each line)
4. I have a file called "smarts.txt" that contains the IQs of every student in the school. Each line in the file has the IQs of every student in a home room. The data file looks something like:

```
123 109 113 89 108 127 96 102 112 132 114 106
112 106 141 108 98 93 95 102 104 98 102
122 109 107 104 94
```

Write the code that will calculate the average IQ.
Also, display the maximum value in each row.
