

Functions exercises

1. Create a function called **subtract** that takes two lists and returns a list that has all of the elements in the first that are not in the second. This function must not remove values from either of the original lists.

- 2.a) Write a function named **isPrime** that will take a positive integer and will return True if the number is prime and False otherwise

- b) Write a function named **primes** that will return a list of all prime numbers less than a given number n. e.g. primes(15) should return [2,3,5,7,11,13]. Use the function **isPrime** from part a) as a “helper function”
